

Journey to engineering degree

from the keyboard's perspective

Marcin Dardziński | Paweł Rzepiński

I've been collecting my keyboard activity for two months while working on my engineering thesis. Let's compare this data against my normal activity after submitting thesis.

The averages for the days of the week while **writing thesis** highly differ from those **after sumbiting** it.

Fridays and Saturdays are my relax time, but I had to devote the latter for the greater good.

Activity plotted throughout the whole period shows that most of the thesis was written is January. There are some gaps due to **weekend breaks**.

After submitting the thesis I took the whole week off.

The distribution of letter frequencies is more similar to the Polish one than English - Kullback-Leibler divergence is 0.11 vs 0.32. Something to expect after writing a 9000 words paper in formal Polish. There are some anomalies though - letters used in common keyboard shortcuts.
